### **Gulf of Maine Point Source Inventory**

This document presents the results of the first phase of NOAA's Gulf of Maine Project, completed in December 1994. The information contained within the database and this report reflect the comments and additional data provided by the reviewers during the summer of 1994. Direct any comments, questions or problems relating to the National Coastal Pollutant Discharge Inventory (NCPDI) Point Source Inventory to Percy A. Pacheco or Daniel R. G. Farrow at the address on the inside of the back cover.

### **Acknowledgments**

The Project Team wishes to thank those individuals in the five jurisdictions of the Gulf of Maine Program who reviewed the data and the draft of this report. The comments and the additional data they supplied improved the reliability of the Point Source Inventory. The Project Team would also like to acknowledge the support provided by NOAA's Coastal Ocean Program and Region I of the EPA. Finally, the Team would like thank our colleagues in the Strategic Environmental Assessments Division for their contributions in completing this project, particularly Manyu Swain and John J. Hayes for assisting in the data review, and Mitchell J. Katz for his editorial comments.

## Introduction

This report summarizes the information contained in the Gulf of Maine Point Source Inventory (hereafter, the "Inventory"). The Inventory includes structural data and pollutant discharge estimates for 273 major and 1,751 minor direct discharging point source facilities located in the U.S. and Canadian watersheds draining to the Gulf of Maine. Estimates of annual and seasonal discharges are made for 15 pollutants for a base year of 1991, using a combination of monitoring data, permit limits, and typical engineering values.

This report and the digital database on which the report is based were developed as part of an interagency agreement between the National Oceanic and Atmospheric Administration (NOAA) and the U.S. Environmental Protection Agency (EPA), to build a point source inventory for the Gulf of Maine Program. The program was organized in 1989 as a cooperative effort between Federal and State (or Provincial) agencies in the United States and Canada to address and act upon environmental issues of concern, such as the sustainable use of the Gulf's marine resources and the prevention of harm to the Gulf ecosystem.

This is the final report from this phase of the project. Comments and additional data received from the review of the January 1994 draft helped refine and improve the database and this report.

**Purpose.** This report provides a concise summary of the number, type, location, and pollutant discharge characteristics of point

source dischargers by watershed. The information contained within the report can provide resource managers with valuable insights as to which facilities are important contributors of pollutant discharges to the coastal waters of the Gulf of Maine.

The report and Inventory were compiled by the Pollution

Inventory is maintained within NOAA's National Coastal Pollutant Discharge Inventory (NCPDI), and is available on two IBM-compatible floppy diskettes (3.5-inch) in an ASCII format. The seven deliverable files archived on the two diskettes contain facility information and pollutant discharge estimates by facility and individual pipe.

**Contents and Organization.** This report is organized into two major sections. The first contains an analysis of the data; the second a series of detailed appendices. The first section includes a characterization of the point source dischargers in the Gulf of Maine, along with discussions on data sources, differences between U.S. and Canadian data, estimation methods, an assessment of data quality including limitations, and potential ways of improving the Inventory. Discharge estimates are aggregated by watershed rather than by county so that estimates can be more easily related to water quality impacts in each watershed.

The 14 appendices in this report contain individual facility characteristics and annual pollutant load estimates; list, for each pollutant, the most significant dischargers; show the percentage of each pollutant estimate based on monitored versus permit, typical pollutant concentration, and other data; present individual estimates of pollutant discharges for all major and significant minor facilities in the study area; present the number and type of facilities in each watershed; summarize, for each watershed, the annual pollutant discharges by major point source category; contain a series of maps showing the

- *The NCPDI Gulf of Maine study area comprises over 68,000 square miles.*
- *The 1990 population within the study area was approximately 6.8 million.*
- *There are 1,553 direct discharging industrial facilities, 378 wastewater treatment plants (WWTPs), and 93 power plants in the Gulf of Maine.*
- *WWTPs and paper mills are the largest dischargers of pollutants.*
- *The Deer Island/Nut Island WWTP complex in Boston, Massachusetts is the single largest single discharger for the majority of pollutants in the Inventory.*
- *The largest industrial discharger in the study area is the International Paper Company in the Sheepscot Bay watershed in Maine.*
- *Approximately 84 percent of the process flow discharges were from facilities located in the United States.*

Sources Characterization Branch of NOAA's Strategic Environmental Assessments Division.  
The Gulf of Maine Point Source

location of major and significant minor point source facilities; and identify the watersheds, hydrologic units, and counties in the region. A glossary of terms has also been included (Appendix 14).

**Study Area.** The Gulf of Maine study area (hereafter, the "study area") is shown in Figure 1. The information in the Inventory can be organized by three spatial units. The first is by watershed.

There are 25 major watersheds

(13 U.S. and 12 Canadian) and 11 minor coastal drainage areas (CDAs) in the study area. The watersheds are also listed in Appendix 9 and 12. In this report, the numbering system used to identify the major watersheds in the United States is the same as that used in NOAA's National Estuarine Inventory. Canadian watersheds are defined using hydrologic information from Environment Canada.

The data can also be organized by hydrologic units, which comprise

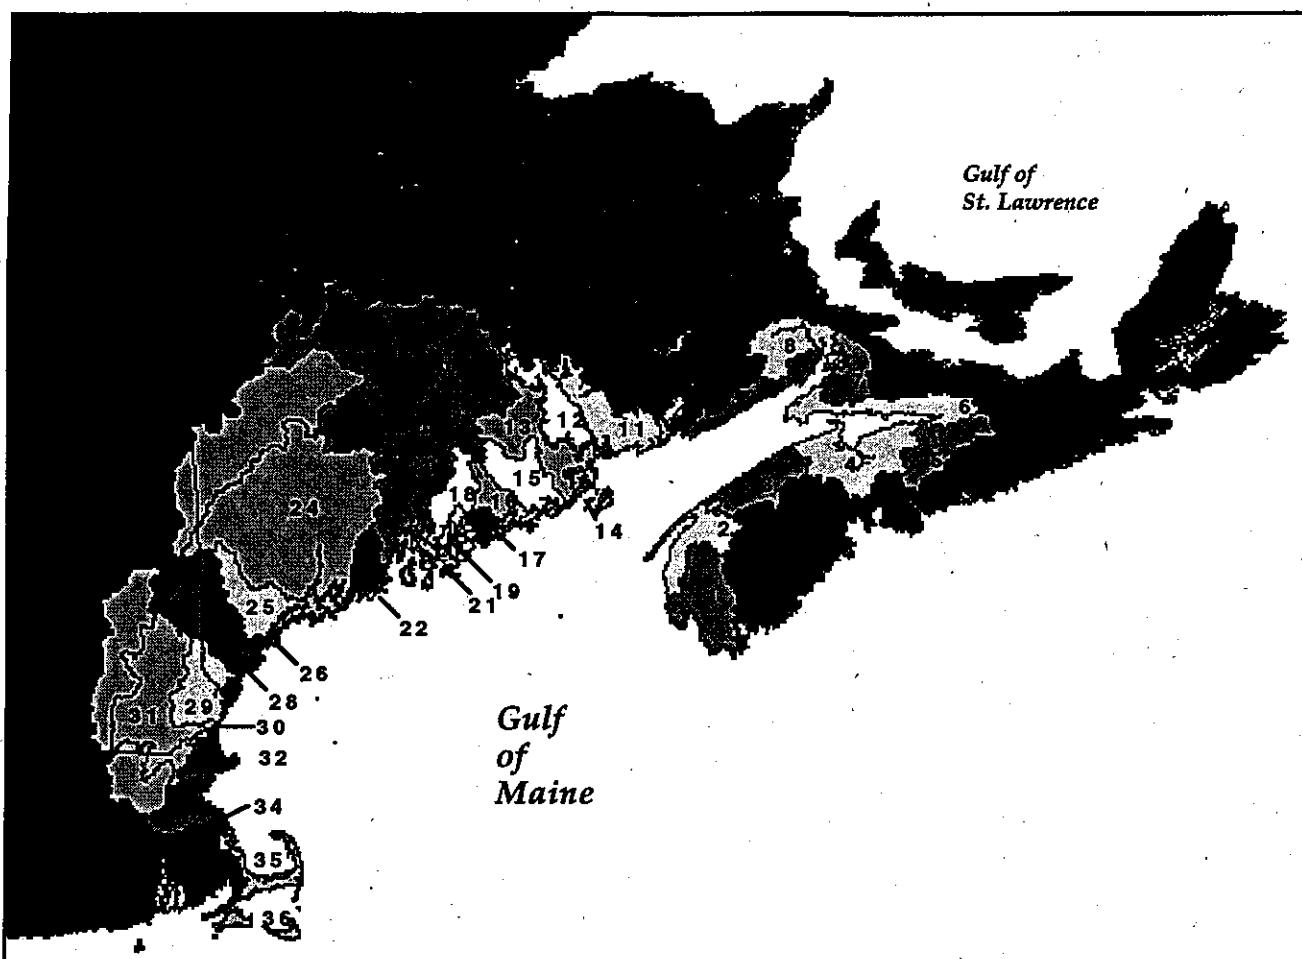

the watersheds. In the United States, the U.S. Geological Survey (USGS) has defined a hydrologic cataloging unit as a geographic area representing all or part of a surface drainage basin, a combination of drainage basins, or a distinct hydrologic feature.

Cataloging units generally have an area of at least 1,800 km<sup>2</sup> (695 mi<sup>2</sup>). In Canada, hydrologic units were identified using the Hydrologic Map Supplements produced by the Water Resources Branch of Environment Canada. Appendix 10 contains a list of the

Table 1. Pollutants in the NCPDI Gulf of Maine Inventory

Pollutant	Description	Annual Units
Flow	Wastewater discharge from a point source. Flow can be process, cooling, sanitary, storm, other, or a combination of these.	Million Gallons
BOD	Biochemical Oxygen Demand; Measure of organic material that can be readily oxidized through microbial degradation.	Pounds
TSS	Total Suspended Solids; Measure of suspended solid materials.	Pounds
Total Nitrogen	Measure of all forms of nitrogen (i.e., nitrate, ammonia, and organic forms).	Pounds
Total Phosphorus	Measure of all forms of phosphorus (i.e., ortho and para compounds).	Pounds
Heavy Metals	A group of elements present in the environment from natural and anthropogenic sources that can produce toxic effects, even in small concentrations.	Pounds
Arsenic		
Cadmium		
Chromium		
Copper		
Iron		
Lead		
Mercury		
Zinc		
Oil & Grease	A mixture of hydrocarbons comprised of hundreds of chemical compounds found in petroleum.	Pounds
FCB	Fecal Coliform Bacteria. Used as an indicator of raw or partially treated human sewage.	Cells

18	N040	Blue Hill Bay	36	N135	Coastal Drainage Area

Note: The Saint John River watershed (C100) is shared by the U.S. and Canada.

57 hydrologic units in the study area.

Counties are the third spatial unit into which the data can be organized. Appendix 11 contains a list of the 61 counties in the study area, along with their 1990 population and areas. A county was included if it was part of any watershed in the study area.

There are currently no discharge estimates available for Quebec, even though a small part of this province is contained in one of the watersheds. This information could be incorporated into the Inventory in the future if the data became available.

**Pollutants in the Inventory.** The Inventory includes estimates for the 15 pollutants listed in Table 1 (including eight heavy metals). These pollutants were included because they represent substances whose presence in the aquatic environment is of concern in terms of both water quality and human health effects. They are also some of the more frequently monitored pollutants.

Table 1 includes the annual units by which each pollutant parameter in the database is measured. Annual flow is given in millions of gallons. Discharges for the remaining pollutants are given in pounds, with the exception of fecal coliform bacteria which is given in cells. In addition, seasonal, monthly, and daily discharge estimates are available for each of the 15 pollutant types in the Inventory.

**Additional Pollutant Discharge Information.** The background files in the database for the Gulf of Maine also include information on the permit limits and

monitored discharges for 305 other pollutant parameters, a subset of the more than 1,600 parameters that can be reported in EPA's Permit and Compliance System (PCS) database. Information for most of these additional parameters such as chlorine, pH, and a suite of organic pollutants is very incomplete, as few permits require facilities to monitor for these pollutants. Typically, facilities are required only to monitor for those pollutants in the effluent judged to be of greatest concern.

**Major/Minor, and Significant Minor Facility Designations.** Point source facilities listed in the database are designated as being either major, significant minor or minor. The definition of these classifications varies between the U.S., New Brunswick and Nova Scotia.

**Major/Minor Designations.** The major/minor designation for the point sources in the U.S. portion of the study area was assigned using a system developed by the EPA. In this system, WWTPs are classified as being major if the flow is greater than one million gallons per day, or if the population served is greater than 10,000. An industrial discharger is classified as a major facility if it scores more than 80 on a numerical rating system. The system assigns points based on an assessment of five characteristics of the permittee's discharges including: 1) toxic pollutant potential; 2) flow/streamflow volume; 3) traditional pollutants; 4) potential public health impacts; and 5) water-quality factors.

In New Brunswick, WWTPs were classified as being major

facilities if the population served was greater than 10,000 per day. Industrial point sources were classified as being major facilities based on discharges of BOD and TSS. Specifically, industrial facilities were classified as being major if they discharged more than 300 pounds of either BOD or TSS per day. In Nova Scotia, major and minor WWTPs and industrial facilities were identified by personnel from the Nova Scotia Department of the Environment.

**Significant Minor Facilities.** In addition to major and minor facilities, significant minors were also identified. Although smaller than the major facilities in the region, significant minor facilities are important contributors of one or more of the pollutant parameters included in the database.

In the U.S., significant minor facilities were defined by the NCPDI as those minor industrial or WWTP facilities with greater than two million gallons per day of process flow. Using EPA's system, a WWTP with a flow of greater than one million gallons per day should have appeared in the PCS database as a major facility. Instead of reassigning the WWTP as a major facility, the NCPDI reclassified it as a significant minor facility. Fortunately, there was only one WWTP in the U.S. portion of the study area that had to be classified as a significant minor facility. Significant minors for Nova Scotia were defined in the same way as in the U.S. New Brunswick defined significant minor WWTPs as those minor facilities serving more than 2,500 people per day. For industries, New Brunswick defined significant minors as those minor facilities discharging more than 75 pounds per day of

BOD or TSS.

**Using the Inventory.** The NCPDI database is intended to be a screening tool to enable region-wide resource allocation and decision-making. From this perspective, it is not necessary that estimates for individual sources be as accurate as they would be for very detailed analyses. The estimates are useful in setting priorities regarding how to manage and protect individual rivers and estuaries in the study area, and can contribute to a better understanding of the impact that point source discharges have on water quality.

## Results

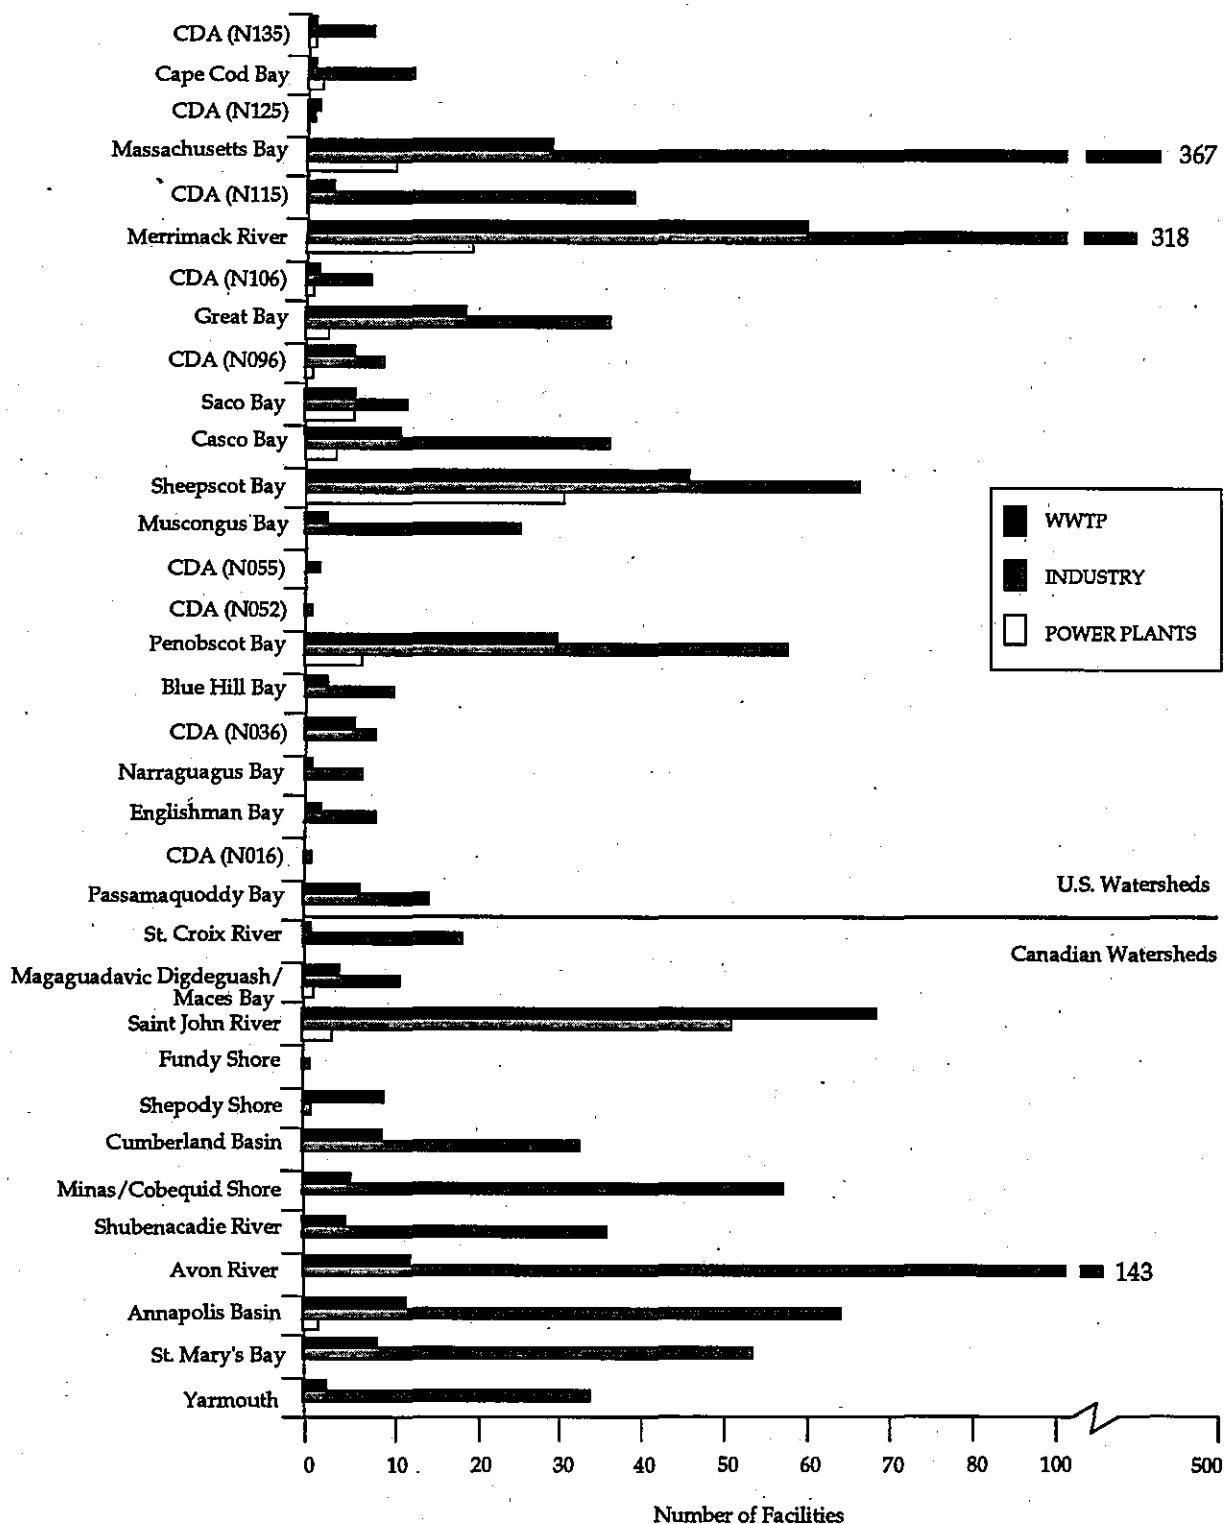

The major results drawn from the analysis of the database are:

- There are a total of 2,024 active point source facilities (273 major and 1,751 minor) in the study area (Appendix 6 and 7). The location of the major and significant minor facilities is shown in the panel maps in Appendix 8.
- Sixty-nine percent of the identified active facilities in the study area are located in the United States.
- There are 1,061 active industrial facilities, 252 wastewater treatment plants (WWTPs), and 85 power plants located in the United States; in Canada there are 492 industrial facilities, 126 WWTPs, and 8 power plants.
- Forty percent of the facilities (803 out of 2,024) in the study area are located in two watersheds in the United States: Massachusetts Bay and Merrimack River (Figure 2). No other single watershed in the

Gulf of Maine accounts for more than eight percent of the facilities in the region (Appendix 3).

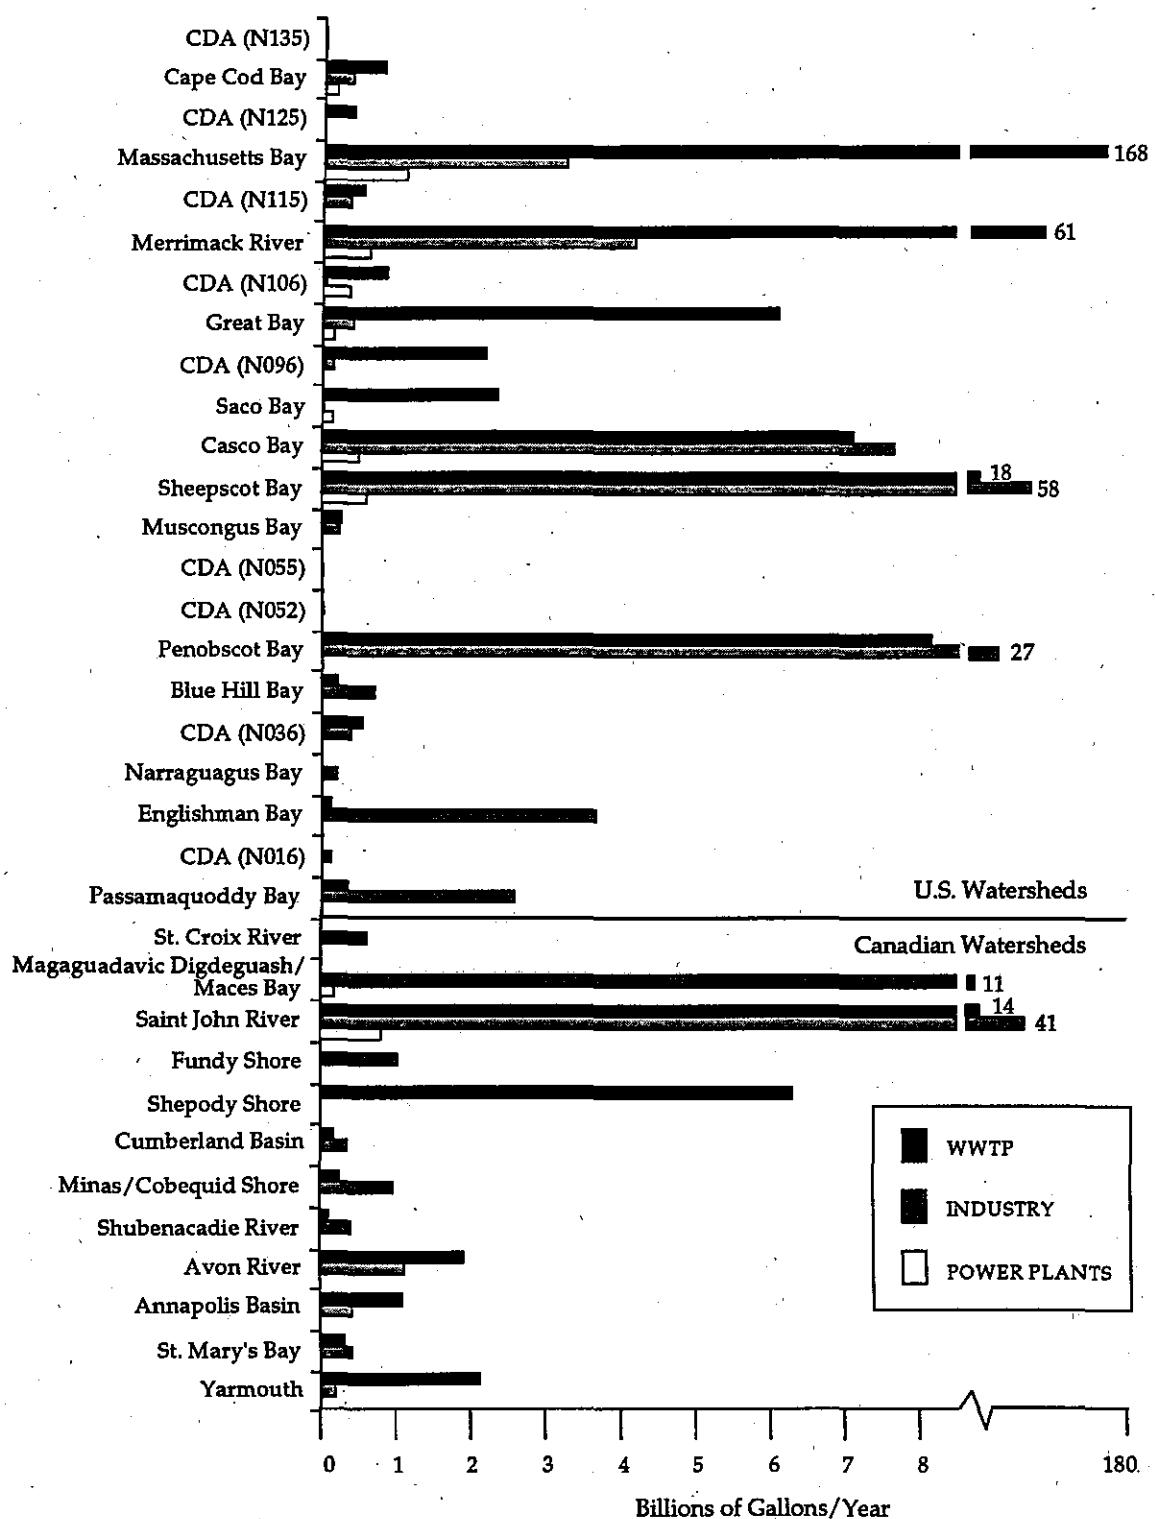

- The major point source dischargers in the study area are WWTPs and pulp and paper mills (Appendix 2).
- Sixty-seven percent of the 378 WWTPs in the study area are located in the United States; the Merrimack River watershed had the greatest number of WWTPs in the U.S. portion of the study area (60). The Saint John River watershed, which is split between the U.S. and Canada, had the greatest number of WWTPs in the Gulf of Maine with 69 (Appendix 3).
- The Massachusetts Water Resources Authority (MWRA) is permitted to discharge effluent from the primary-level treatment complex at Deer and Nut islands, a WWTP complex located in Boston, Massachusetts (Appendix 8). The MWRA-Deer Island/Nut Island complex is the largest overall discharger in the Gulf of Maine. This complex has the highest discharges of any facility for 12 of the 15 pollutants in the Inventory (Appendix 2), and is responsible more than 50 percent of the region's discharge of biochemical oxygen demand (BOD), total suspended solids (TSS), and iron.
- It should be noted that there are three combined sewer overflow (CSO) treatment facilities associated with this complex: Cottage Farm, Prison Point, and Somerville Marginal. A CSO system receives both domestic waste and urban runoff. At times of very high flow, such as during heavy rainfall, the system can overflow resulting in the discharge of raw sewage. Three other CSO facilities in the area, Constitution Beach, Fox Point, and Commercial Point are owned and operated by the Authority but are currently included in the Boston Water and Sewer Commission permit (MA0101192). Discharge estimates for the MWRA-Deer Island/Nut Island complex and for the rest of the Gulf of Maine do not take into account overflow discharges from CSO facilities.
- Of the 1,553 industrial facilities in the Gulf of Maine, 685 (approximately 44 percent) are in the Massachusetts Bay and the Merrimack River watersheds. In the Canadian portion of the study area, the Avon River watershed contains approximately nine percent (143) of the industrial facilities in the study area (Appendix 3).
- The International Paper Company in Maine is the largest industrial discharger in the study area, accounting for the largest industrial discharges of process wastewater, BOD, TSS, chromium, and zinc (Appendix 2).
- Of the 93 power plants in the Gulf of Maine, over 91 percent are located in the United States; the Sheepscot Bay watershed had the greatest number with 31.
- U.S. facilities account for approximately 84 percent of the process flow discharged into the Gulf of Maine (Appendix 5). The Massachusetts Bay watershed had the highest annual process flow (173 billion gallons) in the study area. The MWRA-Deer Island (95 billion gallons) and the MWRA-Nut Island (44 billion gallons) complex (Appendix 1) account for over 80 percent of the total process flow for the watershed.

**Figure 2: Number of Point Source Facilities by Watershed and Major Point Source Category in the Gulf of Maine Study Area, 1991**

Note: There are 10 major and 16 minor point source facilities located in the U.S. portion of the St. John River watershed that discharge to Canadian waters.

**Figure 3: Annual Process Flow by Watershed and Major Point Source Category in the Gulf of Maine Study Area (1991)**

Note: There are 10 major and 16 minor point source facilities located in the U.S. portion of the St. John River watershed that discharge to Canadian waters.

The Sheepscot Bay watershed has the second highest process flow (76 billion gallons) followed by the Merrimack River (66 billion gallons) (Figure 3). The Saint John River watershed in Canada and the U.S. accounts for over 56 billion gallons of process flow annually. Together, these four watersheds account for over 78 percent of the total process flow in the study area.

- The source of the process flow for the Massachusetts Bay and Merrimack River watersheds is primarily WWTPs, while industry is the major source of process flow for the Sheepscot Bay and St. John River watersheds.
- In the U.S. portion of the study area, WWTPs contribute the greatest portion of the pollutant load discharged into the Gulf of Maine (Appendix 3). WWTPs account for over 50 percent of the total load discharged for all 15 pollutants, although industrial facilities are responsible for approximately 38 percent of the chromium discharges in the study area.
- In the Canadian portion of the study area, WWTPs are responsible for the greatest portion of the total pollutant loads for total nitrogen, total phosphorus, arsenic, cadmium, chromium, copper, iron, lead, mercury, oil and grease, and fecal coliform bacteria, while industries have higher discharges of process flow, BOD, TSS, and zinc.
- The 93 power plants in the study area contribute about 72 percent of the total flow discharged from all point source categories (Appendix 3). Most of this flow is once-through cooling water, which has little net

addition of pollutants. However, some power plants have process water discharges that are comparable to loads discharged from major industrial facilities.

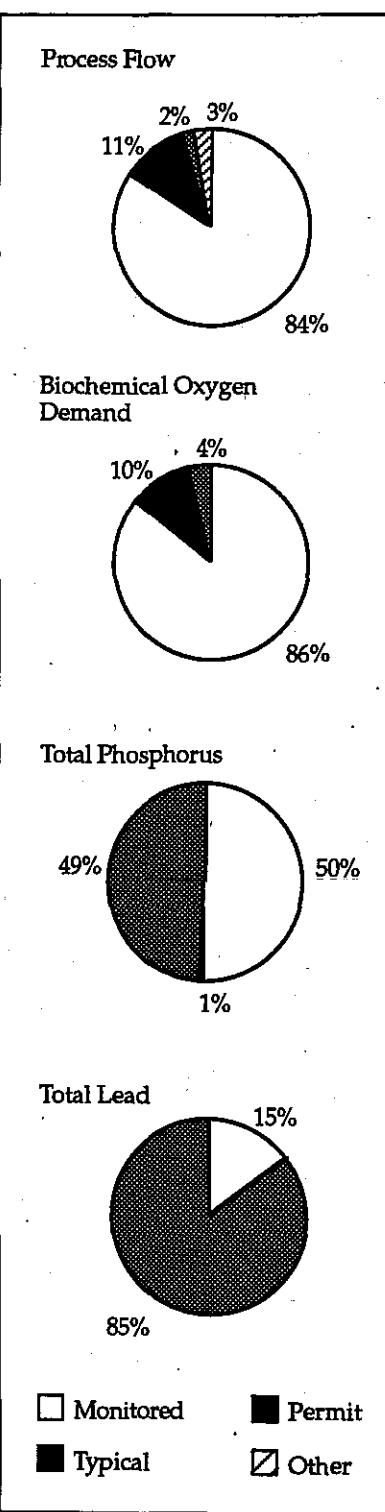

- The amount of monitoring data available varies by pollutant, country, and industry type (Appendix 4 and 5). Overall, the only pollutants within the NCPDI for which monitoring data are generally available in the U.S. are flow, BOD, TSS, and phosphorus (Figure 4 and Appendix 5). For Canadian watersheds, monitoring data were generally available for flow and TSS (Figure 5 and Appendix 5). The remaining parameters for Canadian facilities were estimated using typical pollutant concentration values (Appendix 5).

### Data Sources

Information was gathered from a variety of data sources to build the Inventory of point source dischargers, and to compile the pollutant data needed to make discharge estimates. In this section, U.S. and Canadian data sources are discussed separately.

**United States.** A variety of sources were used to make point source loading estimates for the United States. The major source was EPA's Permit and Compliance System (PCS). In the United States, each point source facility that discharges to surface waters is required to have a National Pollutant Discharge Elimination System (NPDES) permit. The permit contains discharge limits for pollutants that the facility discharges and outlines the facility's monitoring require-

Figure 4. Basis of Loading Estimates for Selected Pollutants in the U.S. Portion of the Gulf of Maine Study Area, 1991

ments. The results of the waste stream monitoring are reported to the State or Federal regulatory agency in monthly or quarterly Discharge Monitoring Reports (DMRs). The DMR data can be obtained either from the PCS database or from State permit files. PCS, a computerized information management system, is used for tracking the permit, compliance, and enforcement-status data for the NPDES.

In addition to the PCS, the 1992 Construction Grants Needs Survey was also used when compiling the Inventory. The Needs Survey is an inventory of all existing or proposed publicly owned WWTPs needing construction to meet the requirements of the Clean Water Act. Data on flow and treatment level were used from the Needs Survey. All data for the United States were received in a digital format.

When possible, the project team filled in missing facility data. For example, when no latitude/longitude information was available, facility locations were estimated using the coordinates of the facility's zip code or the centroid of the city. Watershed codes and hydrologic unit codes were also assigned when necessary.

**Canada.** The data used to make the point source loading estimates for the Canadian point source facilities came from the New Brunswick and the Nova Scotia Departments of the Environment. New Brunswick used a private contractor to assemble the facility data, and data were received in a digital format for major and significant minor facilities.

Personnel from the Department of the Environment in Nova Scotia identified the major facilities in the Province. As with the United States, the project team attempted to fill in missing facility data including location, watershed codes, hydrologic units, and pollutant discharge characteristics.

#### U.S. and Canadian Data Variables

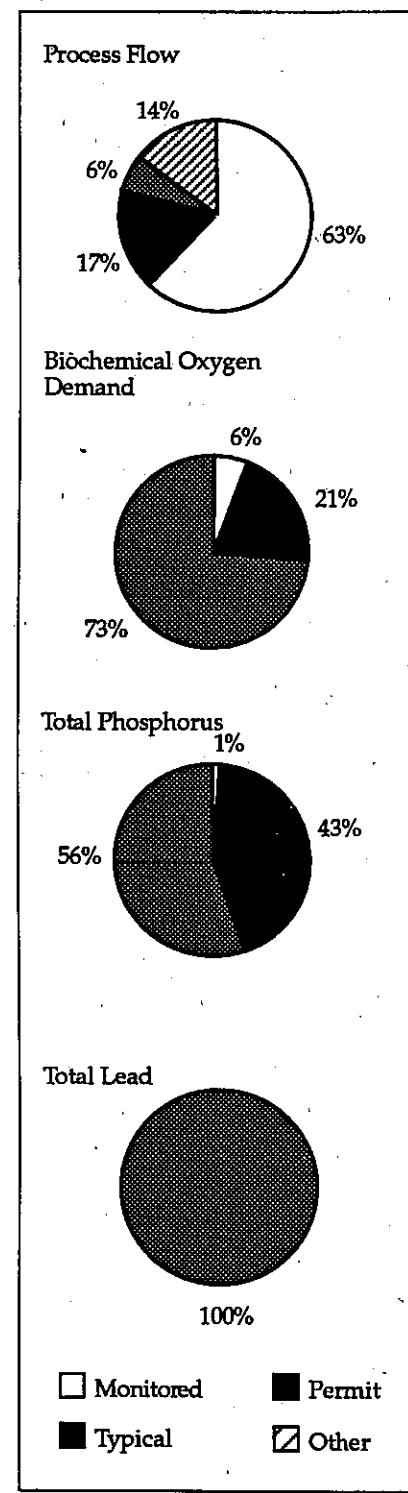

Although most of the variables in the database are the same for U.S. and Canadian facilities, some differences exist. For example, in the United States, the NPDES number, which appears as the variable NPID in the database, uniquely identifies the facility with a nine-character code established by the EPA. In Canada, a different coding system is used. In order to achieve consistency in the Gulf of Maine database, a nine-character "NPID number" was created by the project team for Canadian facilities.

In some cases, a variable used for point source facilities in the United States was not used for Canadian facilities. For example, variables for area code, region, and city code are blank for Canadian facilities, as they were either not appropriate or unavailable. Appendix 13 contains a complete description of the differences between the U.S. and Canadian data variables.

#### Load Estimation Methods

The same load estimation techniques were used for the United States and Canada, once the data received were placed in the

Figure 5. Basis of Loading Estimates for Selected Pollutants in the Canadian Portion of the Gulf of Maine Study Area, 1991

standardized format. The NCPDI load estimation method makes estimates for each active pipe discharging pollutants to surface waters. The pipe-level estimates are then summed to give a facility total.

Estimates are based on monitoring data when available. Monitoring data in the United States are taken from NPDES compliance monitoring results, reported in each facility's DMR. If monitoring data are not available, NPDES permit limits are used. In Canada, facility and discharge data were received from the Departments of Environment of New Brunswick and Nova Scotia. Some monitored and permit data were also available.

If no monitoring or permit data are available, typical pollutant concentrations (TPC) are used to estimate loads. TPCs, developed as part of earlier work for the NCPDI, are assigned based on the type of industrial or commercial activity taking place at the facility or, if the facility is a WWTP, the level of sewage treatment. Daily pollutant discharges are computed, then adjusted to annual discharges by multiplying daily discharges by the days of discharge as reported on the facility's permit application, or assumed for the pipe based on the facility's NCPDI discharge category. Seasonal loads are computed by prorating the annual load using seasonality factors generated from the number of months reporting in the season, or assigned based on the NCPDI discharge category. A more detailed description of the load estimation methods can be found in the NCPDI Point Source Methods Document published in 1993.

### How Good is the Inventory?

The Inventory characterizes the number, type, and location of direct discharging facilities in the study area, and provides the best estimates available of the pollutant discharges from these facilities. The value of this information to the user depends on the completeness, timeliness, and accuracy of the data compiled.

A key component of this work was the effort to gather and use as much monitored pollutant discharge data as possible to improve the accuracy of the discharge estimates. Ideally, all pollutant discharge estimates would be based on monitoring data. Unfortunately, the available monitoring data for the U.S. and Canada are incomplete.

**Completeness.** An extensive effort was made to generate a comprehensive inventory of facilities in the study area. The inventory of facilities received for the U.S. was fairly complete. Following the review of the draft report and database, the New Brunswick Department of the Environment personnel provided a list of additional facilities along with pollutant discharge characteristics for these and other facilities in the database. Their input significantly improved the New Brunswick discharge estimates.

For Nova Scotia, although the Department of Environment provided a fairly complete list of the major and minor facilities in the study area, data on individual facility characteristics (e.g., latitude/longitude, facility type, flow, and pollutant concentrations) was very incomplete. The

location of all facilities in Nova Scotia had to be approximated using city latitude/longitude coordinates, and pollutant discharge estimates were based almost entirely on typical pollutant concentrations.

It should be understood that compiling a complete and current inventory of facilities in an area is difficult. In any given time period, some facilities start or change operations, others cease operations either temporarily or permanently, and some change ownership and name. Resolving discrepancies in the exact number, type, and discharge characteristics of facilities in an area is time consuming and often unsuccessful. Nevertheless, the Project Team believes the Inventory to contain a fairly complete listing of the dischargers in the study area, although additional work would continue to improve the accuracy of the inventory.

**Timeliness.** The data in the Inventory were collected for a base year of 1991, and are most representative of discharges for that year. For screening-level assessments, loading estimates can be considered reasonably representative of discharges from 1991 to 1993. In general, this assumption is better for discharges from WWTPs, which vary less over time, than from industrial activities, which are more sensitive to changes in production levels tied to economic conditions.

The user should keep in mind that many of the discharge estimates were based on TPCs. As noted above, TPCs or typical pollutant concentrations are assigned to an industrial facility or WWTP when no monitoring or permit data is available. Subse-

quent to the completion of the first draft of this report, the NCPDI developed a new set of TPCs for WWTPs (Appendix 14). These values were based on some of the most recent literature and have now been incorporated into the database and this report. For industrial facilities, however, TPC values are based on information that is 10-15 years old. An assessment has not yet been made to determine if these typical concentrations are still representative of the discharge category. Because such a large proportion of the discharge estimates are based on TPCs, it is a potential source of error, particularly for discharges from industrial facilities.

**Availability of Monitoring Data.** The availability of monitoring data varies by pollutant, as was seen in Figures 4 and 5. In the United States, monitoring data for flow, BOD, TSS, and phosphorus are generally available, while the availability of metals data is poor. For example, approximately 82 percent of the estimate for BOD for U.S. facilities in the study area is based on monitoring data. For nitrogen, arsenic, cadmium, and chromium, however, less than 10 percent of the estimates are based on monitoring data (Appendix 5). For the Canadian facilities, while permit monitoring data were generally available (i.e., for New Brunswick), for flow and TSS, the availability of monitoring data for the 13 other pollutants was very poor (Appendix 5).

**Nitrogen and Phosphorus.** Although the NCPDI makes nutrient discharge estimates using total nitrogen and phosphorus data, it should be noted that facilities sometimes monitor for other forms of these two

nutrients. For example, while 94 percent of the monitoring data for phosphorus was for total phosphorus, none of the monitoring data for nitrogen was for total nitrogen. Other forms of nitrogen such as ammonia, dithiocarbonate, and nitrate are more frequently monitored.

Although efforts were made to collect and use monitoring data, the fact that the vast majority of permits for point source facilities in the study area only require monitoring for conventional parameters raises the question of whether monitoring for additional pollutants should be required, at least for the major facilities that contribute the bulk of the pollutant loadings. The estimates in the NCPDI can be used to identify those major facilities for which additional permit requirements should be considered.

**Accuracy of the Estimates.** As discussed above, the capability to generate accurate discharge estimates is limited by the scarcity of monitoring data for the majority of pollutants covered in the Inventory. As a result, for many pollutants carried in the NCPDI, load estimates were based on assumptions about typical pollutant concentrations in the waste stream, the volume of flow in the pipe, and the type of wastewater (i.e., process, cooling, a combination of both, or domestic sewage effluent). These assumptions, while based on best engineering judgement, may result in inaccurate or even totally erroneous estimates in some cases. In addition, there is no way to quantify the error by assigning numerical confidence limits to the estimates. However, by tagging each discharge estimate

with a data source and computational basis code, an effort has been made to provide the user with a means to evaluate the relative confidence that can be placed on the estimate. A future goal is to make more comparisons between NCPDI estimates and monitoring studies of individual plants as a means of improving the accuracy of the data.

### How Can the Inventory Be Improved?

There are a number of ways the Inventory can be improved. One of the most important is locating and incorporating additional monitoring or permit data for point source facilities in the study area, particularly for Nova Scotia. In addition, there are other components that could be added to enhance the overall characterization capabilities for the Gulf of Maine Program.

**Completing the Canadian Portion of the Inventory.** The Inventory can be significantly improved with additional monitoring and facility information for Nova Scotia. More complete data would result in more accurate and complete discharge estimates for the study area.

**Refining Minor Facility Information.** The accuracy of the data in the Inventory could also be increased by improving information for minor point source facilities. While New Brunswick and Nova Scotia provided additional information for minor facilities during the review, most of the pollutant discharge estimates for minor facilities not only in the Canadian portion of the

study area, but also in the U.S. still rely heavily on TPCs. Discharge data for these smaller facilities would help improve the accuracy of the database.

**Improving Spatial Resolution.** The eight-digit hydrologic cataloging unit is the smallest watershed-based spatial unit by which the information in the current Inventory can be aggregated. Users at the State and Provincial level may need to aggregate data by smaller watershed units such as 10-, 12-, or even 14-digit subbasins for more detailed watershed management decisions. Assigning facilities to these subbasins can be accomplished using a geographic information system if the digital boundary files defining the smaller watersheds are available. Alternatively, reporting the river reach number for U.S. facilities, or the Canadian equivalent would greatly improve the accurate aggregation of facilities into small watershed units. The reach number is an 11-digit code developed by the USGS and the EPA and is made up of the eight-digit USGS cataloging unit code and the three-digit EPA segment number.

**Increasing Access to the Inventory.** Putting all or a portion of the Inventory into a desktop information system would make the data more accessible to a broader group of managers and analysts. These desktop systems can be designed to have a user-friendly interface that provides simple mapping, analysis, and data manipulation capabilities. Systems can be expanded with additional data and analysis capabilities as the need arises to

address specific water quality problems.

**Overlay of Other Data.** There are a variety of other data that could be added to the Inventory to improve the utility of the Gulf of Maine Project. For example, data generated by the States to satisfy the Section 305b requirements of the Clean Water Act could be overlaid with discharge data to pinpoint pollution sources. Information on shellfish closures maintained by NOAA could also be used to help correlate shellfish closures with pollutant discharges. Finally, NOAA monitors benthic organisms and analyzes sediments through its National Status and Trends Program to gage the health of the nation's coastal waters. This information could be used to correlate the presence or effects of pollution with point source discharges. The same type of information from Canada could be used in a similar manner.

**Adding Nonpoint Sources of Pollution.** Though not an improvement to the point source inventory, adding a nonpoint source component would provide a more complete picture for the region, as discharges from nonpoint sources such as farmlands and urban areas may also be significant sources of pollution in the Gulf of Maine. The Project Team is currently working on developing estimates of nonpoint source discharges for the U.S. portion of the drainage. Incorporation of nonpoint source estimates for the Canadian portion would create a complete pollution source characterization inventory for the Gulf of Maine.

Abbreviations: BOD, Biochemical Oxygen Demand; TSS, Total Suspended Solids; TN, Total Nitrogen; TP, Total Phosphorus; As, Arsenic; Cd, Cadmium; Cr, Chromium; Cu, Copper; Fe, Iron; Pb, Lead; Hg, Mercury; Zn, Zinc; O&G, Oil and Grease; PCB, Fecal Coliform Bacteria; WWTP, wastewater treatment plant; -, indicates that either there were no estimates for that parameter or there were no facilities in that point source category in the watershed.

Notes: 1) Percentages might not add up to 100 due to rounding. 2) There are 10 major (six WWTPs and four industries) and 16 minor (eight WWTPs and eight industries) point source facilities located in the U.S. portion of the Saint John watershed that discharge to Canadian waters.

Abbreviations: NP, number of pipes; PD, percent of total discharge based on data source; BOD, biochemical oxygen demand; TSS, total suspended solids; FCB, fecal coliform bacteria.

Note: There are 1,398 facilities with 2,059 pipes in the U.S. portion of the study area and 626 facilities with 687 pipes in the Canadian portion of the study area. The number of facilities by pollutant and source of estimate can not be reported because of double counting facilities with multiple pipes.

**Appendix 8.**  
**Maps of Major and Significant**  
**Minor Point Source Facilities**  
**in the Gulf of Maine Study Area**

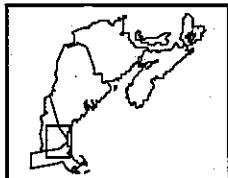

## Panel Map Index 1

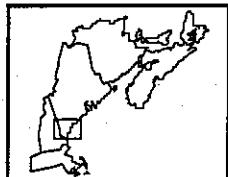

Panel 1. Cape Cod Bay. Page 8-3. There are four major facilities (two wastewater treatment plants and two industries) plotted on this panel map. Plymouth wastewater treatment plant (WWTP), a municipal facility (MA0100587), is located in the city of Plymouth, within Plymouth County, Massachusetts. It is the largest discharger shown on this map with a process flow of 807 million gallons per year.

Panel 2. Massachusetts Bay. Page 8-5. There are 40 major facilities (19 wastewater treatment plants and 21 industries) plotted on this panel map. MWRA WWTP- Deer Island and Nut Island (MA102351), a municipal complex of facilities, is located in the city of Boston, within Suffolk County, Massachusetts. It is the largest discharger shown on this map with a process flow of 139,154 million gallons per year.

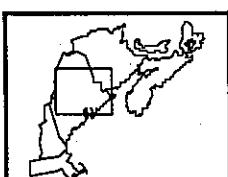

Panel 3. Merrimack River/Great Bay. Page 8-9. There are 86 major facilities (52 wastewater treatment plants and 34 industries) plotted on this panel map. Greater Lawrence S.D. WWTP (MA 0100447) is a municipal facility located in the city of North Andover, within Essex County, Massachusetts. It is the largest discharger shown on this map with a process flow of 13,502 million gallons per year.

Panel 4. Saco Bay/Casco Bay. Page 8-15. There are 20 major facilities (nine wastewater treatment plants and 11 industries) and one significant minor WWTP plotted on this panel map. The S.D. Warren Co. (ME0002321), a paper mill, is located in Westbrook, within Moosehead County, Maine. It is the largest discharger shown on this map with a process flow of 678 million gallons per year.

Panel 5. Sheepscot Bay/Muscongus Bay. Page 8-19. There are 35 major facilities (24 wastewater treatment plants and 11 industries) and two significant minors (facilities engaged in operating fish hatcheries or preserves) plotted on this panel map. International Paper Co. (ME0001937), a paper mill facility, is located in the city of Jay, within Franklin County, Maine. It is the largest discharger shown on this map with a process flow of 17,886 million gallons per year.

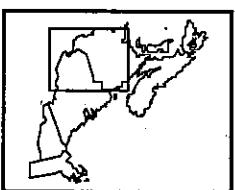

Panel 6. Penobscot Bay/Blue Hill Bay. Page 8-21. There are 22 major facilities (16 wastewater treatment plants and six industries) plotted on this panel map. Great Northern Paper Inc. (ME0000175), a paper mill, is located in the city of East Millinocket, within Penobscot County, Maine. It is the largest discharger shown on this map with a process flow of 7,766 million gallons per year.

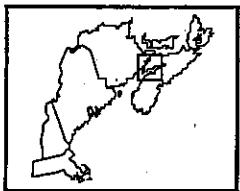

## Panel Map Index 2

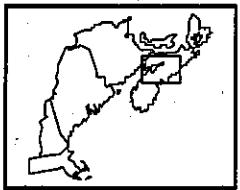

Panel 7. Narraguagus Bay to Magaguadavic Digdeguash/Maces Bay. Page 8-23. There are nine major facilities (three wastewater treatment plants and six industries) and five minor facilities (one wastewater treatment plant and four industries) plotted on this panel map. Sea Farms Canada Inc., (NBI379-90), a facility engaged in operating fish hatcheries or preserves, is located in St. George City, within Charlotte County, New Brunswick. It is the largest discharger shown on this map with a process flow of 7,221 million gallons per year.

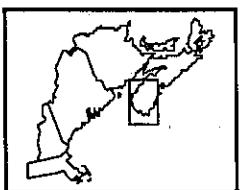

Panel 8. Saint John River. Page 8-25. There are 36 major facilities (14 wastewater treatment plants and 22 industries) and 14 significant minor facilities (10 wastewater treatment plants and four industries) plotted on this panel map. Irving Pulp & Paper Ltd. (NBI-0052), a pulp mill facility, is located in Saint John City, within Saint John County, New Brunswick. It is the largest discharger shown on the map with a process flow of 7,271 million gallons per year.

Panel 9. Fundy Shore to Cumberland Basin. Page 8 - 31. There are three major facilities (one wastewater treatment plant and two industries) and two significant minor facilities (one wastewater treatment plant and one industry) plotted on this panel map. Moncton Sewage Commission WWTP (NBS-12), a municipal facility, is located in the city of Moncton, within Westmoreland County, New Brunswick. It is the largest discharger shown on the map with a process flow of 6,387 million gallons per year.

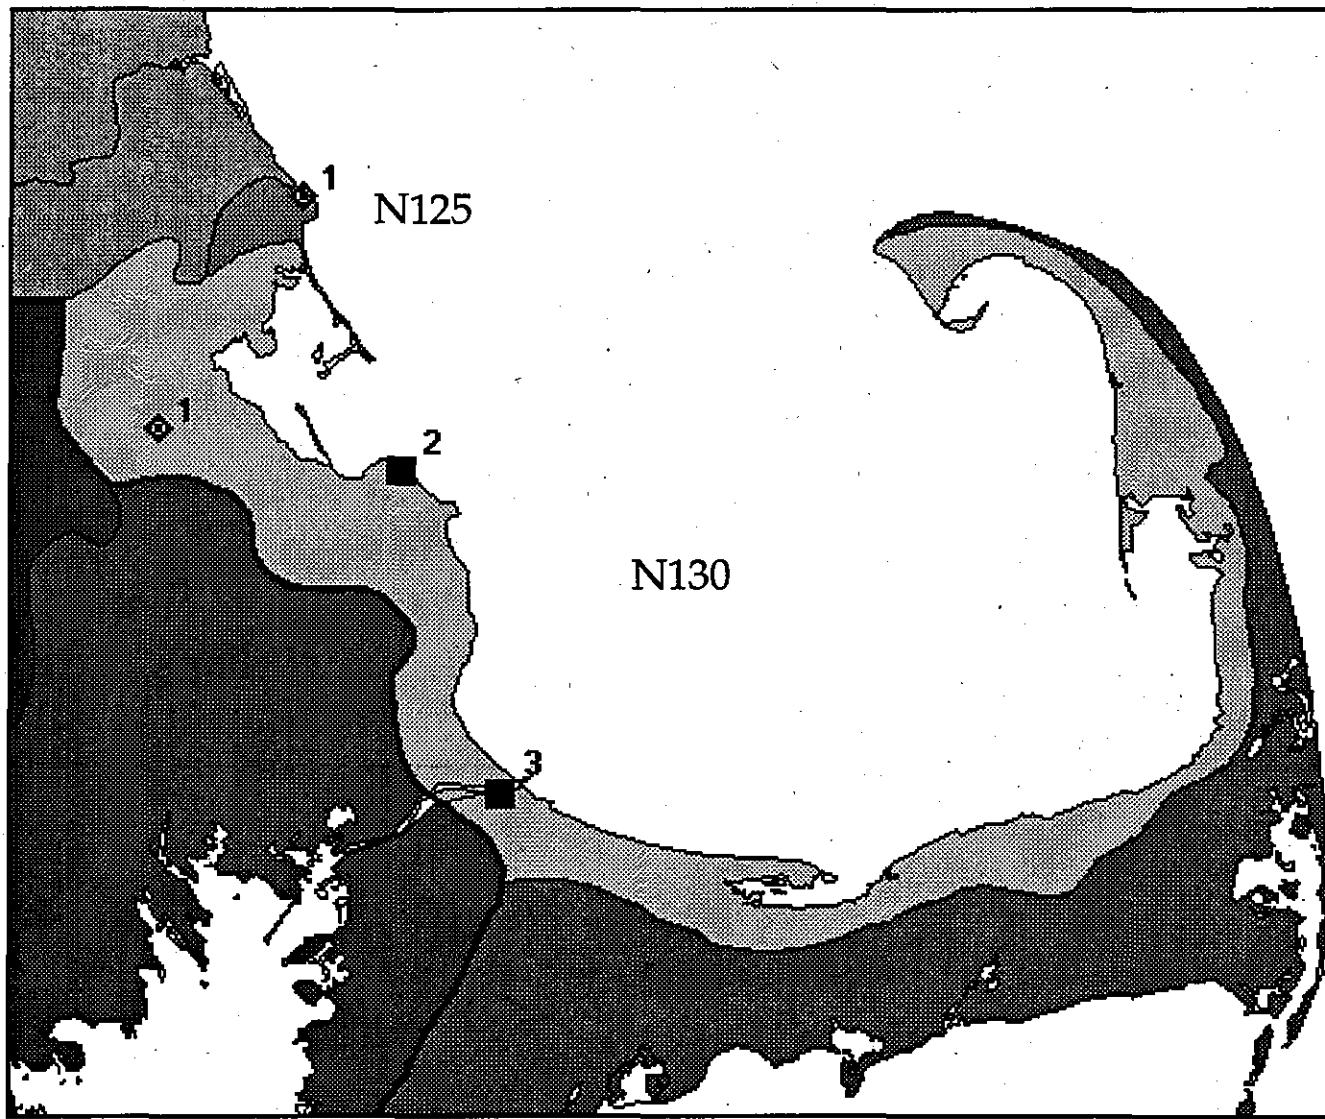

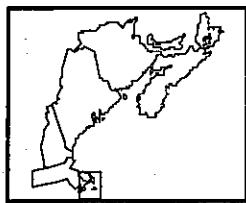

Panel 10. Minas/Cobequid Shore to Avon River. Page 8 - 33. There are 13 major facilities (one wastewater treatment plant and 12 industries) plotted on this panel map. Kings County Regional WWTP (NSWWTP48), a municipal facility, is located in the city of New Minas, within Kings County, Nova Scotia. It is the largest discharger shown on this map with a process flow of 794 million gallons per year.

Panel 11. Annapolis Basin to Yarmouth. Page 8 - 35. There are six major facilities (one wastewater treatment plant and five industries) plotted on this panel map. Yarmouth STP (NSWWTP01), a municipal facility, is located in the city of Yarmouth, within Yarmouth County, Nova Scotia. It is the largest discharger shown on this map with a process flow of 2,117 million gallons per year.

\* The Massachusetts Water Resources Authority (MWRA) is permitted to discharge affluent from the two primary primary treatment plants, Deer Island and Nut Island. The location of the authority is shown on the map as the Deer Island Treatment Plant location. The Nut Island Treatment Plant is not shown on this map.

Notes: 1) The Map Ref. # refers to the Panel Map Number, Watershed, and Facility [eg. Panel Map # (02), Watershed (N035), Facility (001)]. 2) Basis of loading estimate codes: M = monitoring data; P = permit data; T = data derived from typical pollutant concentrations; O = other data; B = value from both monitoring and typical pollutant concentration, permit data, or other data. 3) An asterisk in the Major/Minor Code flags a significant minor identified by the New Brunswick Department of Environment. 4) A @ in the Major/Minor Code flags a significant minor identified based on process flow greater than or equal to 2 MGD. 5) Annual process flow: 0 = process flow estimated to be zero for this facility; - = no data available for this facility.

Appendix 13.  
Differences Between Canadian and  
U.S. Data Variables in the  
Gulf of Maine Point Source Inventory

---

---

## **Appendix 13. Differences Between Canadian and U.S. Data Variables in the Gulf of Maine Point Source Inventory**

This appendix provides a description of several variables in the 3 basic files (facility, monitoring and permit) of the inventory which are defined differently for Canadian facilities. The appendix also lists the variables that do not have any data for Canadian point source dischargers. When appropriate, New Brunswick and Nova Scotia variables are discussed separately. For a detailed description of the variables listed here and the other variables in the data base, please refer to the NCPDI Point Source Methods Document (NOAA, 1993).

### **FILE 1 - Facility File**

#### **NPID - National Pollutant Discharge Elimination System (NPDES) Number**

New Brunswick: A unique identification number is assigned for the NPID, with the two first characters (NB) identifying the province name and the third identifying the facility as an industrial or municipal plant (i.e. I for industry and S for municipal). The permit number is used for industrial and municipal point sources as identified by the New Brunswick Department of the Environment.

Nova Scotia: A unique identification number is assigned for the NPID, with the two first characters (NS) identifying the province name. The identification number as defined by the Nova Scotia Department of the Environments is used for industrial point sources. A unique sequential identification number following the characters "WWTP" is assigned to the municipal point sources.

#### **MADI - Major Discharge Indicator**

New Brunswick: Municipal point sources are classified as major facilities if the population of the service area is above 10,000. Industrial point sources are classified as major facilities if the BOD or TSS discharge is above 300 pounds per day. This report includes only those significant minors as defined by NOAA in the body of the report. The New Brunswick Department of the Environment identified 12 municipals and 5 industries as significant minors.

Nova Scotia: Municipal point sources are designated as major facilities if the wastewater discharge is 1 MGD or greater. Industrial point sources were classified as major facilities by Dan Hiltz from the Nova Scotia Department of the Environment.

#### **STTE - State Code**

An abbreviation of the Province's name is used as an identifier for the state code (i.e., NB for New Brunswick and NS for Nova Scotia).

#### **STATE - State FIPS Code**

A value of 90 was assigned to New Brunswick and 91 for Nova Scotia by the PSC Branch to designate the state code.

#### **CNTY - County Code**

New Brunswick: A three digit code assigned by the New Brunswick Department of the Environment designates the county.

Nova Scotia: The first three first characters of the county name was assigned by the PSC Branch as the county code.

## **Appendix 13. Differences Between Canadian and U.S. Data Variables in the Gulf of Maine Point Source Inventory**

### **FCU - Facility U.S.G.S. Hydrologic Cataloging Unit Code**

New Brunswick: The 8 characters of the Hydrologic Watershed Unit Number assigned by the New Brunswick Department of the Environment designates the FCU.

Nova Scotia: The 3 characters of the Hydrologic Watershed Unit Number as it appears in the Hydrometric Map Supplement, Atlantic Provinces, published by the Water Resources Branch, Water Survey of Canada, Environment Canada, 1986 designates the FCU.

### **EDACODE - Estuarine/Coastal Drainage Area Code**

New Brunswick and Nova Scotia: The assignment of this code represents the major Canadian watershed as defined by the Gulf of Maine Council on the Marine Environment and by Environment Canada. The names of the watersheds are designated by the Gulf of Maine Council on the Marine Environment. The watershed boundaries are defined by the Hydrometric Map Supplement , Atlantic Provinces, published by the Water Resources Branch, Water Survey of Canada, Environment Canada, 1986.

### **SIC - Standard Industrial Classification Code (1987 Facility Description)**

New Brunswick: The industrial classification code assigned by the New Brunswick Department of the Environment is used as the SIC code and the U.S. Industrial Classification Code.

Nova Scotia: The industrial classification code is assigned by the facility name and facility description derived by the PSC Branch at NOAA.

### **FLAT, FLON - Facility Latitude and Longitude (Degrees, minutes, seconds)**

New Brunswick: The latitude and longitude of all point sources are provided by the New Brunswick Department of the Environment. Coordinates for all point sources, except for power plants, are determined to within ±5 meter accuracy in the field using a Geographical Positioning System. Coordinates for power plants are determined from 1:50,000 topographic map sheets.

Nova Scotia: The latitude and longitude of all point sources are assigned by the PSC Branch at NOAA based on city coordinates of the point source location.

### **NOTE: THE FOLLOWING ARE VARIABLES THAT DO NOT CONTAIN ANY DATA FOR THE CANADIAN POINT SOURCE DISCHARGERS**

For the New Brunswick and Nova Scotia point sources inventory: MRAT, CITY, KEYPTNUM, EDACLASS, FLLCODE1 FLLCODE2 FLLCODE3, REAC, FFID, GPCT, IACC, IADT, PRET, INCL, STBA, AREACODE, STUDY0, STUDY1, STUDY2, STUDY3, STUDY4, STUDY5, REGION, FACILQC.

For the Nova Scotia point sources inventory: BAS6, RWAT, EPST, EXMY, TYPA, TYPO.

### **FILE 2 - Monthly Discharge Monitoring Report (DMR) File**

New Brunswick: These variables do not contain any information in the DMR File: MDML, NODI, LCUC, and LQUC

Nova Scotia: All variables, except NPID, DSCH and MLOC do not contain any information in the DMR File

## **Appendix 13. Differences Between Canadian and U.S. Data Variables in the Gulf of Maine Point Source Inventory**

### **FILE 3 - Permit Requirements and Loading (PRL) File**

New Brunswick: The variable PIPE does not contain any information in the PRL File.

Nova Scotia: All variables, except NPID, DSCH, PDSG, PIPE, WAST, and PIAC do not contain any information in the PRL File. All pipes for all facilities are assumed by the PSC Branch at NOAA to be active pipes and to discharge process wastewater.

## Appendix 14. Glossary

---

---

## Appendix 14. Glossary

This section is an alphabetical listing of technical terms used in this document which may not be familiar to the reader. Terms with an asterisk have different definitions in Canada. Refer to Appendix 13 for further explanations of these differences. For a description of the variable names, please refer to Appendix 1a and Appendix 1b of the NCPDI Point Source Methods Document (NOAA, 1993).

**Biochemical Oxygen Demand (BOD).** The quantity of dissolved oxygen used in the biochemical oxidation of organic matter in a specific time, at a specified temperature, and under specified conditions. BOD values provide a somewhat standard measure of how much oxygen will be required to degrade a waste, and therefore reflect the effect waste may have on fish or other aquatic organisms that require oxygen to live.

\* **Coastal Drainage Area (CDA).** A relatively small watershed not draining to a major estuary in the in the region. The CDA is defined by hydrologic units identified by the U. S. Geological Survey or by Environment Canada.

**Direct and Indirect Dischargers.** A direct discharger is a facility that discharges its effluent directly into a receiving water, such as a stream, river, estuary, or ocean. An indirect discharger is a facility that discharges its effluent into a sewer system for treatment by a wastewater treatment plant.

**Discharge Category Code.** The coding scheme used in the NCPDI that links categories of industrial dischargers to their respective typical pollutant concentration values. A discharge category is comprised of a group of industrial or municipal facilities that engage in similar manufacturing or waste-producing processes, and thus are assumed to have similar types and levels of pollutant discharge. Facilities are assigned to one of 89 discharge categories based on the facility's Standard Industrial Classification code.

**Discharge Monitoring Report (DMR).** The form used to report to a regulatory agency the results of a discharger's effluent monitoring. DMRs are submitted on a regular basis (usually monthly for major facilities and most minor facilities; quarterly for small dischargers), as required under the discharger's National Pollutant Discharge Elimination System permit.

**Estimated Discharge Load.** An amount of a pollutant discharged over a specific period of time that has been computed using either monitoring or typical flow volumes and typical pollutant concentration values. Because of the assumptions involved in using typical pollutant concentration values, these load estimates are considered less accurate than those based entirely on monitoring data.

\***Fecal Coliform Bacteria (FCB).** A measure of the fecal coliform bacteria found in a sample of water. FCB are the bacteria that are present in the intestines or feces of warm-blooded animals. They are often used as indicators of the presence of human pathogenic organisms carried in sanitary sewage. Their concentrations are expressed as number of cells per 100 milliliters of sample.

**Heavy Metals.** These include Arsenic (As), Cadmium (Cd), Chromium (Cr), Copper (Cu), Iron (Fe), Lead (Pb), Mercury (Hg) and Zinc (Zn). For the purpose of this report they are measures of the individual constituents listed above as a total of all their different forms. For example, Chromium is a measure of all forms rather than just the hexavalent form of Chromium.

## Appendix 14. Glossary

\* **Hydrologic Cataloging Unit.** A geographic area defined by the U. S. Geological Survey (USGS) representing all or part of a surface drainage basin, a combination of drainage basins, or a distinct hydrologic feature. The cataloging unit is the smallest of the four hydrologic units used by the USGS to define the boundaries of drainage basins throughout the country.

**Industrial Discharger.** A facility that, as a result of manufacturing products from raw materials, discharges a contaminated effluent to the environment. The second of the three major categories of point source dischargers in the NCPDI. Industrial dischargers are the most complex category for which to make loading estimates because of the variation in facility size, production levels and waste-streams within a single discharge category.

\* **Major or Minor Facility.** The terms used to classify dischargers according to their relative importance as pollutant sources. The criteria used to make major and minor assignments were developed by the EPA's Office of Water Enforcement and Permits. Different guidelines are used for wastewater treatment plants and industrial dischargers. Major wastewater treatment plants are those that discharge over one million gallons per day on average, or serve a population greater than 10,000 people, or discharge to surface waters that have severe water quality problems. Industrial dischargers are classified using a numerical rating system that takes into account discharge volume, effluent toxicity, level of conventional pollutant discharge, potential human health impacts, and water quality factors. Because major facilities contribute the largest share of pollutant discharges, they are the main focus of the data collection effort in the NCPDI.

**Major Watershed.** One of the 25 watersheds in the Gulf of Maine study area which drains to a major estuary in the study area. The watershed is defined by hydrologic units identified by the U. S. Geologic Survey or by Environment Canada.

**Monitoring Discharge Load.** An amount of a pollutant discharged over a specific period of time computed using monitoring flow volumes and pollutant concentrations based on monitoring data. Estimates based on reported monitoring data are considered the most accurate values in the Inventory.

**National Estuarine Inventory (NEI).** The NEI is a series of interrelated projects and activities initiated by NOAA to develop a national estuarine data base and assessment capability. The NEI identifies 90 estuaries, which account for approximately 90 percent of the estuarine surface water of the three coasts of the contiguous U.S. The NEI acts as a framework for the integration of information gathered on an estuary-by-estuary basis by NOAA's Strategic Assessment Branch.

\* **National Pollutant Discharge Elimination System (NPDES) discharge permit.** The permit that sets limits on the amounts or concentrations of pollutants that a municipal, industrial, or commercial facility is allowed to discharge into surface waters. The permit is written by either the state regulatory agency or the EPA and revised every five years. It specifies which pollutants are regulated (e.g., wastewater, phosphorus, mercury), and how frequently the permit holder must monitor its effluent for the pollutants listed on the permit. If the permit holder violates the terms of the permit, it is liable for penalties under the Water Quality Act of 1987.

**Needs Survey Data Base.** A data base initiated in 1973 by the EPA to comply with the Federal Water Pollution Control Act Amendments and has been updated every two years so that EPA may report their findings to Congress. This data base is the major source of data for all existing or proposed wastewater treatment plants and includes information characterizing facility

## Appendix 14. Glossary

**location, flow capacity, influent and effluent characteristics, treatment processes, population served by each WWTP, construction cost estimates, and projection for future treatment needs.** There are approximately 24,000 facility records in the 1986 Needs Survey data base.

**Nutrients.** Chemical elements or substances, such as nitrogen and phosphorus, that are essential for plant and animal growth.

**Oil and Grease (O&G).** All forms of oil and grease that are measured from petroleum derived sources. Included are light aromatics as well as tars. Oil and grease from animal fats, vegetable oils, or rendering operations can also be measured in the test.

**Operating Days.** The number of days in a calendar year that an industry or wastewater treatment plant was either known or assumed to have operated and released an effluent. In the NCPDI load estimation methodology, operating days are used to adjust daily load estimates to annual estimates.

**Once-through Cooling Water.** Water typically drawn from a surface water source that is passed only once through heat exchange equipment and then is discharged back into the receiving water.

**Permit Compliance System (PCS) Data Base.** This is a computerized EPA data management information system for tracking permit compliance and enforcement status data for the NPDES. The 1987 data base consists of more than 5 million records on over 75,000 active discharge permits issued nationally by the EPA.

**Point Source Category.** One of the three major point source categories classified in the NCPDI inventory. WWTPs, Industry, and Power Plants.

**Power Plants.** A facility that generates electricity by either the burning of fossil fuels, or nuclear fission. The third of the three major categories of point source dischargers in the NCPDI. Although power plants usually do not release large quantities of pollutants, if they use once through cooling water to remove heat from the condenser units, they release tremendous volumes of wastewater. They are carried as a separate point source category in the NCPDI because the high value of wastewater discharged would tend to distort their relative importance as pollutant sources.

**Process Wastewater.** Wastewater which contains by-products of manufacturing, commercial, or domestic activities that is released to either a wastewater treatment plant or, after treatment, to a receiving water. Sources of process wastewater include: process water, septic tank waste, demineralizer backwash, salt water brine, industrial waste chemicals, ship ballast water, sump drain water, wash water which is an integral part of production, heating water, metal cleaning wastewater, and low volume wastewater. Once-through and recycled cooling water are not considered polluted wastewater.

\* **Receiving Water.** The name of a river, stream, tributary, lake or other body of water into which the facility effluent is discharged.

**Seasonality Factor.** A coefficient used in computing estimates of seasonal loads of pollutants discharged by the facilities. Seasonality factor is computed from the seasonal discharge days for a pipe or assumed, based on the facility's discharge category code. Many classifications of

## Appendix 14. Glossary

industries, such as seafood processes and fruit and vegetable processors, only operate when the material they process is harvested. This coefficient accounts for the seasonal fluctuation in effluent production by these industries.

**\* Standard Industrial Classification (SIC) code system.** A coding system developed by the Office of Management and Budget to classify establishments according to the type of activity in which they are engaged. The SIC is intended to cover the entire field of economic activities: agriculture, forestry, fishing, hunting, and trapping, mining, construction, manufacturing, transportation, communications, electric, gas, and sanitary services, etc.

**Total Nitrogen.** The sum of all forms of nitrogen.

**Total Phosphorus.** The sum of all forms of phosphorus.

**Total Suspended Solids (TSS).** Total amount of solid matter in a representative water sample that is retained on a membrane filter. It includes all sediment and other constituents which is suspended in a fluid.

**Typical Pollutant Concentration (TPC).** The concentration of a pollutant that is assumed to be present in a discharger's effluent when actual monitoring or permit data are not available. There is a TPC for each of the 15 pollutants and the 88 discharge categories in the NCPDI. TPC values are drawn primarily from the EPA's Development Documents for Effluent Limitations Guidelines and Standards.

A new set of TPCs for wastewater treatment plants (WWTPs) was used for this project. The source of the TPCs was primarily from *Managing Wastewater in Coastal Urban Areas* (1993) published by the National Academy Press of the National Research Council. The other source of information used in developing the new TPCs for WWTPs was the Environmental Protection Agency's 1990 Needs Survey. The TPCs used to develop estimates for WWTPs when no monitoring or permit data were available is shown below.

Pollutant Parameter <sup>†</sup>	Untreated	Treatment Level				
		Primary	Advanced Primary	Secondary	Advanced Secondary	Tertiary
BOD	250	69	39.3	25	10.9	5
TSS	250	63	50	30	12	8.5
TN	35	23	19	19	11	3
TP	8	8	4.2	2.8	1	1
FCB	5E7	2E5	2E4	2E3	1.53E3	1E3
As	0.0155	0.0155	0.0155	0.014	0.00825	0.0025
Cd	0.0144	0.01265	0.01265	0.0065	0.00392	0.00135

OG	50.7	27.6	19.4	11.2	8.4	5.6

## Appendix 14. Glossary

Pollutant Parameter <sup>†</sup>	Untreated	Primary	Treatment Level			
			Advanced Primary	Secondary	Advanced Secondary	Tertiary
PCB	19	11.9	2.075	1.9	1.05	0.2
CHP	0.8	0.8	0.7	0.6	0.5	0.3

Abbreviations: BOD, biochemical oxygen demand; TSS, total suspended solids; TN total nitrogen; TP, total phosphorus; FCB, fecal coliform bacteria; As, arsenic; Cd, cadmium; Cr, chromium; Cu, copper; Fe, iron; Pb, lead; Hg, mercury; Zn, zinc; OG, oil and grease; PCB, polychlorinated biphenyl; CHP, chlorinated hydrocarbon pesticide.

<sup>†</sup>Concentrations for BOD, TSS, TP, TN, As, Cd, Cr, Cu, Fe, Pb, and Zn are in mg/l. Concentrations of Hg, PCB, and CHP are in ug/l. Concentrations of FCB is in cells per liter.

**Wastewater Treatment Plant (WWTP).** A facility that receives wastewaters (and sometimes runoff) from domestic and/or industrial sources, and by a combination of physical, chemical, and biological processes reduces (treats) the wastewater to less harmful byproducts. The first of the three categories of point source dischargers in the NCPDI. WWTPs are an important source of pollutant loadings. The loadings estimated for WWTPs are considered more accurate than those for industries or power plants. Definitions of the various levels of treatment follows.

*Untreated* - no treatment; pollutant effluent concentrations estimated to be the same as influent concentrations.

*Primary Treatment* - A physical process that involves gravity separation of settleable and floatable solids from the influent waste stream. Other physical separation processes such as fine screens and filters can be included in this treatment step. Primary treatment results in the removal of about 30 percent of carbonaceous biochemical oxygen demand from domestic sewage.

*Advanced Primary Treatment* - A low-dose, chemically enhanced primary treatment process defined as the addition of a metal salt or other primary coagulant in concentrations between 5 mg/l and 100 mg/l with or without the application of a polymer, prior to primary clarification.

*Secondary Treatment* - Conventional biological treatment system, often classified as either suspended (e.g., activated sludge) or attached growth system (e.g., trickling filters) with a diverse culture of microorganisms to break down organic matter in the wastewater, oxidizing a portion and converting the remainder to biological solids. Some soluble constituents (i.e., heavy metals) are removed by adsorption to the biomass. Some nutrient removal occurs through incorporation into the generated biomass.

*Advanced Secondary Treatment* - Innovative secondary treatment processes that provide higher BOD/TSS removal than conventional secondary treatment processes. With advanced secondary treatment , there is typically an enhanced removal of phosphorous and increased sludge production. Advanced secondary treatment systems in particular can be configured to remove nitrogen and/or phosphorus.

*Tertiary Treatment* - Advanced cleaning of wastewater that goes beyond secondary or biological treatments. Tertiary treatment typically removes nutrients such as nitrogen and phosphorus, as well as most BOD and TSS. Nutrient removal is accomplished with high lime and granular activated carbon, or high lime, granular activated carbon and reverse osmosis.

## **NOAA's SEA Division**

NOAA's Strategic Environmental Assessments (SEA) Division mission is to conduct comprehensive, interdisciplinary assessments of multiple resource uses for the Nation's coastal and oceanic waters, including the Exclusive Economic Zone. Assessments are made in the areas of pollution sources, human activities, physical environments, and biogeography and are intended to help identify strategies to enable decision-makers to balance conservation and development. To accomplish this objective, the SEA Division conducts environmental assessments, synthesizes data into information systems, and organizes this material into regional and national environmental reports and data bases.

### **PSC Branch**

The Pollution Sources Characterization Branch of NOAA's SEA Division conducts assessments of coastal pollution sources and discharges. The cornerstone of the program is the *National Coastal Pollutant Discharge Inventory* (NCPDI). The NCPDI is a comprehensive data base and computational framework that contains seasonal and annual pollutant loading estimates for 15 pollutant parameters for all major categories of point, nonpoint, and riverine sources located in the Nation's coastal watersheds. These estimates can be aggregated by county, USGS hydrologic cataloging unit, or estuarine watershed. Pollutant estimates in the Inventory are for a base year of 1991.
